

VSTF Event-Cascade and Claim-Governance Layer

A detected transition becomes a countable outcome only after locked, auditable gates are passed.

Rejected or unresolved observations remain auditable

- No Q_{dist}: proxy signal only; do not count as accepted transition.
- No localization: candidate event remains unresolved or rejected.
- No retention: acute response, not stabilized outcome.
- No V_{dom}: generic state movement, not domain-valid success.
- No complete denominator: may be state-valid but cannot support VSTE/cost-yield claims.

Locked numerator and denominator

$N_{VST}^{op} = \sum_k A_k$, where $A_k = Q_{dist} * L_k * R_k(\tau^*) * V_{dom,k}$
Reference validity Z_k and probabilistic p_k are reported separately from A_k .
Cost-normalized claims additionally require Q_B^{acct} and a declared boundary B .

Reviewer-facing interpretation

VSTF is not a new transition detector. It is a pre-specified adjudication and claim-governance layer placed after or alongside transition detection, before a detected event enters an outcome numerator.
